

MINI PROJECT

PROJECT TITLE : Password Strength Checker with
User Registration.

SUBMITTED BY : Lokeshwar Reddy kukkala

DATE OF SUBMISSION : 29/09/2025

INTRODUCTION :

Passwords are the first line of defense in online security.

Weak passwords make accounts vulnerable to hacking and unauthorized access. This process focuses on building a password strength checker that guides users to create stronger and more secure passwords.

OBJECTIVES :

The main aim of this project is to help users create secure passwords. It automatically evaluates password strength, gives suggestions for improvement, and integrates this checking system into a user registration process.

The project also increases awareness about the importance of strong passwords.

TOOLS & TECHNOLOGIES :

This project is developed using Python with the Flask framework for backend operations. HTML, CSS, and Javascript are used for the frontend interface.

Regular expressions (re) are applied to validate password rules. The system runs on a standard web browser for testing and demonstration.

SYSTEM DESIGN :

When a user enters their details in the registration form, the password is sent to the backend server. The backend checks the strength of the password based on rules such as length, uppercase and lowercase letters, numbers, and special characters.

The result is sent back to the user, showing whether the password is weak, medium, or strong, along with suggestion for improvement.

IMPLEMENTATION :

The password is validated step by step. It must be at least 8 characters long, include both uppercase and lowercase letters, contain numbers, and have at least one special character.

Common weak patterns such as “12345678” or “password” are rejected. The user gets live feedback on the strength before completing registration.

OUTPUT :

The system displays a simple registration page where users can enter a username and password. When a weak password is entered, suggestions are shown to make it stronger.

After improving the password, the system shows “Strong” and allows the user to register successfully.

RESULT & DISCUSSION :

The project was successfully implemented and tested. Users who entered weak passwords immediately got suggestions such as “Add a number” or “Use a special character”.

This ensures that users are encouraged to create stronger and more secure passwords during registration.

CONCLUSION :

The password strength checker project demonstrates how simple rules can improve security in user registrations. It educates users about strong password practices and prevents the use of weak passwords. In the future, the system can be extended to include secure password storage, hashing algorithms, and two-factor authentication for even higher protection.
